## Analysis of Tranche Maturity calculation methods for the Securitization External Rating Based Approach (SEC-ERBA).

## Introduction

The European Banking Authority (EBA) Guidelines ${ }^{1}$ detail the appropriate methods of determination of the regulatory capital pertaining to securitization outlined in the Basel III regulation. Among the requirements the setting of regulatory capital floors (RCFs) focuses on tackling systemic liquidity risks through a hierarchy of approaches.

In this paper, we focus on the implementation of the securitization external rating based approach (SEC-ERBA) in calculating the RCF for a given maturity. We have compared the two possible methods leveraging the Legal Maturity $\left(M_{L}\right)$ and the Weighted Average Maturity (MwaM) respectively with the aim of identifying the minimal floor level.

The study is conducted for over 2,000 EMEA RMBS, AUTO and ABS securities as well as over 9,000 tranches of US and European CLOs across all past vintages. In our observation, $38 \%$ of these securities show a difference in RCF value between the two methods, representing an overall average difference of $€ 5,980$ per $€ 1,000,000$ of invested notional balance. Table 1 below shows the difference in regulatory capital between the two methodologies across asset classes.

Table $1 \quad$ Notional Difference in RCF by Asset Class

| ASSET CLASS | SECURITIES | AVG ReGULATORY CAPITAL DIFFERENCE BETWEEN THE Mı AND Mwam Methods |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | $\triangle$ PRESENT | PERCENTAGE | $M_{\llcorner }$RCF | M wam RCF | NOTIONAL $\triangle$ |
| ABS | 321 | 88 | 27\% | 139,168.87 | 111,311.08 | 27,857.79 |
| AUTO | 225 | 166 | 74\% | 162,929.75 | 135,314.48 | 27,615.27 |

## Weighted Average Maturity Assumptions

We compared the two possible calculation methods ${ }^{2}$ using the Legal Maturity $\left(M_{\llcorner }\right)$and the Weighted Average Maturity (MWAM) respectively. When using the Mwam method the tranche maturity may be determined with different sets of assumptions for the cash flows used in its calculation as outlined in the framework published by the EBA33.

## Prepayment Rate Assumptions

The EBA conducted a consultation on relevant assumptions to be used when determining the WAM ${ }^{4}$ values. Institutions may consider one of the three following options ${ }^{5}$ :
(a) the prepayment rate considered in the base case scenario of the pricing prepayment assumptions ${ }^{6}$ of the transaction, with a 20\% cap;
(b) the lowest historical prepayment rate of the asset class observed quarterly, or at least annually, over the longest available period, with a minimum of 5 years', in the country in which the assets were originated;
(c) the average observed quarterly prepayment rate throughout the life of the transaction since its inception, with a minimum of 1 year's data.

CLO transactions do not feature a reported CPR rate that could be leveraged for assumptions (b) and (c). The study of CLO tranches for different prepayment rates ranging from 0 to $20 \%$ annually ( $2.5 \%$ increments) reveals that the lowest RCF corresponds to the highest rate. This paper focuses on the $20 \%$ CPR assumption for CLO securities as per the option (a) cap.

Default, Loss Rate and Recovery Assumptions
In addition to the above criterium an assumed 0\% CDR for any performing portfolio was established as a norm across the asset class. The Loss Rate and Recovery Lag on these defaults are therefore nullified as well under this framework.

[^1]
## RMBS \& ABS Analysis

Our focus in this study is to maximize CPR assumptions so as to obtain the RCF value using the MwAM method. For EMEA RMBS and ABS securities we have leveraged our extensive data set to determine the maximum CPR assumption between option (b) and (c).

We have retained 37 eligible asset types across 9 European countries for which the (b) option may be leveraged thanks to a sufficient data history. In each case where the lifetime CPR of option (c) was unavailable, lower or covered under 1 year of history we used the option (b) assumption instead for the RCF determination.

CPR Assumption Breakdown by Asset Types

The below table presents a list of the 19 main RMBS and ABS asset types belonging to the seven main countries selected in the EMEA region with an added miscellenaous category. We can observe that, for eight of these, over $60 \%$ of securities present a lower RCF using the Mwam method and that seven of these are either backed by Auto Leases or Prime Auto Loans. The average difference ranges between 190 and 369 basis points for these asset types.

Table $2 \quad$ RCF Difference $(\Delta)$ for the $M_{L}$ and $M_{\text {wam }}$ Methods by Asset Type

| COUNTRY | ASSET TYPE | SECURITIES | RCF DIFFERENCE BETWEEN THE M ${ }_{\text {L }}$ AND M M ${ }_{\text {wam }}$ METHODS |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | $\triangle$ PRESENT | PERCENTAGE | RCF M ${ }_{\text {L }}$ | RCF Mwam | AVG DIFF |
| FRANCE | ABS - Automobiles - Prime | 23 | 23 | 100\% | 4.39\% | 2.70\% | 169bp |

[^2]
## Method Comparison Breakdown by Country

The below table presents a country breakdown of all $A B S$ and RMBS securities across different seniorities. We focus here on the average difference ( $A V G \Delta$ ) in RCF between the $M_{L}$ and $M_{\text {wam }}$ methods. The impact when using the $M_{\text {wam }}$ method is most prevalent among German and French securities where $57 \%$ of all tranches across all seniorities present a lower resulting RCF with an average difference of 251bp and 236bp for these countries' subsets respectively.

If we focus on the seniority of the securities, we can observe that $34 \%$ of the 810 senior tranches present a difference in RCF against $25 \%$ and $6 \%$ for Mezzanine and Subordinated tranches respectively. However this difference is significantly higher for the Mezzanine and Subordinated subsets with 403bp and 433bp on average against only 60bp for Senior tranches.

Table $3 \quad$ Regulatory Capital (RCF) Difference ( $\Delta$ ) for the $M_{L}$ and $M_{\text {wam }}$ Methods by Seniority

| COUNTRY | REGULATORY CAPITAL DIFFERENCE BETWEEN THE ML AND Mwam Methods |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | SUBORDINATE |  |  | MEZZANINE |  |  | SENIOR |  |  |

| GERMANY | 9 | 0\% | Obp | 20 | 65\% | 445bp | 15 | 80\% | 40bp |
| PORTUGAL | 7 | 0\% | 0bp | 11 | 0\% | 0bp | 15 | 27\% | 24bp |
| BELGIUM | 3 | 0\% | Obp | 8 | 50\% | 378bp | 3 | 0\% | 0bp |
| Total | 561 | 6\% | 433bp | 820 | 25\% | 403bp | 810 | 34\% | 60bp |

## Method Comparison Breakdown by Rating

The table below presents the breakdown of observed RCF differences across ratings. We notice that the highest differences concern securities rated Ba 1 to Ba 3 with a over 500 bp of difference on average. The differences observed for Aaa classes is significantly lower than that of lower rated securities (Aa1 to B3). This can be explained by the preponderance of senior tranches in this subset which incur a lower five year risk weight value (RW ${ }_{5}$ of $20 \%$, vs $70 \%$ for non-senior) resulting in a narrower gap in RCF values.

The securities rated Caa1 and below presented no difference while very few securities rated B2 and B3 did. Most of them present a maturity $M_{\text {wam }}$ longer than five years which is therefore capped and identical across the two methods. This is due to the sequential nature of repayments in their cash flow waterfall. A few subordinate tranches also present a difference as they belong to older transactions which are typically already partially redeemed.

Table $4 \quad$ RCF Difference $(\Delta)$ for the $M_{L}$ and $M_{\text {wam }}$ Methods by Rating

| RATING ${ }^{9}$ | SECURITIES | REGULATORY CAPITAL DIFFERENCE BETWEEN THE ML AND Mwam Methods |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | $\triangle$ PRESENT | PERCENTAGE | RCF M ${ }_{\text {L }}$ | RCF Mwam | AVG $\triangle$ |
| Aaa | 425 | 160 | 38\% | 2.70\% | 2.08\% | 62bp |
| Aa1 | 125 | 48 | 38\% | 5.24\% | 2.28\% | 297bp |
| Aa2 | 106 | 42 | 40\% | 5.30\% | 3.05\% | 225bp |
| Aa3 | 103 | 62 | 60\% | 4.10\% | 2.90\% | 120bp |

## Method Comparison Breakdown by Vintage

The below table presents a breakdown by vintage of the data set. The outstanding tranches of older transactions tend to be lower down the capital structure and also belong to asset types with lower prepayment profiles. Therefore while they are shorter dated on average within their respective categories they also present a typically slower amortization profile.

In contrast the prepayment rates for the underlying pools of more recent securities present a higher CPR on average resulting in a faster amortization profile. They are also located higher in the capital structure on average and are therefore repaid earlier in sequential order. These competing factors result in a mixed picture on the frequency and average RCF difference between methods presented in the table below.

Table $5 \quad$ RCF Difference $(\Delta)$ for the $M_{L}$ and $M_{\text {wam }}$ Methods by Vintage

| VINTAGE | SECURITIES | REGULATORY CAPITAL DIFFERENCE BETWEEN THE MLAND MwaM METHODS |  |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | :---: |
|  |  | $\Delta$ PRESENT | PERCENTAGE | RCF M | RCF Mwam | AVG $\Delta$ |  |  |
| 2022 | 207 | 74 | $36 \%$ | $22.08 \%$ | $19.59 \%$ | 248 bp |  |  |
| 2021 | 261 | 98 | $38 \%$ | $19.88 \%$ | $17.10 \%$ | 278 bp |  |  |

## CLO Analysis

The research conducted was performed under a 20\% CPR assumption as this is the maximum rate available under option a) of the EBA framework. We also compared the two methods under a $0 \%$ CPR scenario so as to evaluate the impact of prepayments on MWAM RCF results. It was conducted on both US and European CLO transactions.

Method Comparison Breakdown by Rating

The high prepayment rate brings a large portion of the redemptions forward in time and results therefore in a set of lower $M_{\text {wam }}$ values than those observed under the lower bound scenario ( $0 \%$ CPR) for the same universe of securities. A greater difference in RCF is observed between the two methods for these tranches. We also observe that for a greater proportion of securities, particularly down the capital structure, these values are under the 5 year cap and create a difference as well.

European CLO securities tend to present a lower RCF for the Mwam method more frequently ( $90 \%$ of tranches) for the highest rated tranches but with a lower average difference of 27 basis points against 31 for their US counterparts. We observe that these US securities were issued 4 years ago on average and 2 months later than European Aaa rated tranches. While this difference may seem small, it does tip a higher percentage of corresponding $M_{\text {wam }}$ values below the 5 year cap. This results in a much higher percentage of European securities presenting an RCF difference.
The overall average reduction across all credit quality steps is 57 bp for European deals for $37 \%$ of tranches against 32 bp for $42 \%$ of tranches in the US. The below table presents the results using the scenario of a $20 \%$ CPR assumption as outlined in subsection (a) of the EBA framework for the metrics outlined by the calculations of figures ${ }^{10} 2$ to 5 :

Table $6 \quad$ CLO RCF Difference $(\Delta)$ for the $M_{L}$ and $M_{\text {wam }}$ Methods by Rating

## Method Comparison Breakdown by Vintage for CLO Aaa rated Tranches

The homogeneity of the CLO asset class as well as the high number of deals enables us to study the impact of the vintage on the difference between the $M_{\llcorner }$and $M_{\text {wam }}$ methods. We notice that the older the security is the more likely it is to present a lower RCF using the M Mam calculation. For securities issued up to year 2018 over $90 \%$ of the tranches studied present an RCF difference. This rate then falls steadily for more recent vintages. Older Aaa rated CLO securities present this wider gap more frequently on average for $M_{\text {wam }}$ and $M_{L}$ due to their seniority in the capital structure.

Similarly we observe the decrease in the value of $M_{\text {wam }}$ as we consider securities of older vintages. In contrast $M_{\llcorner }$sees little impact as the vast majority of these securities present a legal maturity 5 years or more into the future regardless of their vintage. The average importance of the gap stops following this linear trend for securities issued in the last 2 years. For these subsets it is calculated based on a smaller proportion of the cohorts (less than 50\%) with more tenuous differences being observed for a given year which increases statistical noise in the end result.

Figure 1. Method impact on RCF by Vintage (Aaa CLO tranches)

## Summary of Notional Differences Using the Mwam Method for ABS, RMBS and CLOs

Here we consider an investment of notional EUR 1,000,000 and determine the amount spared by an investor by leveraging the $M_{\text {wam }}$ Regulatory Capital calculation with the highest CPR assumption allowed. We notice high discrepancies between asset classes on the proportion of securities benefiting from the use of the $M_{\text {wam }}$ method. We can observe that the resulting average difference for these ABS and RMBS asset types ranges from EUR 6,500 to 39,000 on a single position of this size. For CLOs the average difference varies significantly between the different vintages and ratings as detailed previously.

Table $7 \quad$ Notional Differences between the two Methods

| COUNTRY | ABS-RMBS |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

[^5]
## Conclusion

The minimum regulatory capital to be set aside for a securitized asset position may be determined using the legal maturity of the tranche for simplicity. The alternative method leveraging the weighted average maturity, although more complex, yields a lower or equal capital charge to be applied for any given security. This second method presents an increased risk sensitivity across the universe of transactions. For any security considered the highest CPR assumption within the limits set by the regulator corresponds to the RCF calculation through the use of the M MAM method.

Senior tranches at the top of the credit stack are where differences are observed most frequently across the set of available securities. These discrepancies are distributed unevenly across vintages as is observable for CLO tranches where older deals are affected in greater proportions for the same rating and level of seniority. The average size of the gap between the two methods also tends to increase with the age of issuance for these securities.

The highest differences in RCF calculations are observed for short dated notes lower down the capital structure. The higher risk weights ${ }^{12}$ assigned to them by the regulator mean that variations in the maturity value impact the RCF ${ }^{13}$ determination to a greater extent. However many of these tranches' WAM breach the 5 year cap which nullifies the difference between the two methods. This can be observed with recently issued Mezzanine and Subordinate tranches presenting differences between the two methods less frequently. This can be mitigated by using the highest possible CPR value as an assumption for deals amortizing their tranches sequentially.

The use of $M_{\text {wam }}$ in order to determine the RCF for a position on the tranche of a securitization transaction increases risk sensitivity in a significant portion of cases when compared against $M_{L}$. The gap observed is non negligeable in most of these cases as demonstrated by the results outlined.

[^6]
## Appendix: Calculation of Regulatory Capital

The capital requirement(CR) for a given tranche is calculated as $8 \%$ of the risk weight (RW) associated for a given maturity. The latter may be calculated either using the WAM or Mt method as per the EBA framework.

## Appendix 1: Maturity Calculation

The tranche maturity is the effective maturity that is remaining and is expressed in years. In order to calculate it, the institution can choose between two possible ways as defined in article 22 of the "Basel III Document Revisions to the securitisation framework".

The Maturity variable $X$ referred to in Figure 1 and Figure 2 above is to be calculated as $M_{\llcorner }$or $M_{\text {wAM }}$ as per the SEC-ERBA guidelines.

The method to determine the maturity $M_{\perp}$ based on the Final Legal Maturity $\left(M_{F}\right)$ of the tranche can be found on Figure 3:
Figure $2 \quad M_{L}=1+\left(M_{F}-1\right) \times 0.8 \quad$ (floored at 1 , capped at 5 , in years)

The method to determine the maturity MWAM is as per Figure 4 using the cash flows of the tranche (CFt) paid out at time $t$ to the noteholder (principal, interests and fees as applicable):

Figure $3 \quad M_{\text {WAM }}=\frac{\sum_{t}\left(t \times C F_{t}\right)}{\sum_{t} C F_{t}}$
(floored at 1, capped at 5, in years)

The Cash flows $C F_{t}$ are compiled with the following lower bound case assumptions: 0\% Constant Prepayment Rate (CPR), 0\% Constant Default rate (CDR), 0\% Loss Rate, 0\% Recovery Lag, 30/360 day count. The options for these assumptions are discussed in the next section.

## Appendix 2: Risk Weight Interpolation and Regulatory Capital Calculation

The risk weight is determined according to two distinct scales for senior and non-senior tranches respectively set out by the regulation. Each scale lays out a set of 1 year and a set of 5 year risk weight values (RW1 and RW5) corresponding to the rating of the tranche.

The risk weight (RW) of the tranche is then calculated based on the tranches' thickness ( $T$, see figure 4 ) per Article 257 of the CRR and using an interpolation (RWX) of RW1 and RW5 for the tranche maturity ( $($ ) (see figure 3). The resulting capital requirement (CR, see Figure 5) is calculated as $8 \%$ of the RW value.

Figure 4

$$
R W_{X}=\mathrm{RW}_{1}+(X-1)\left(\frac{R W_{5}-R W_{1}}{5-1}\right)
$$

Figure $5 \quad \mathrm{RW}=\mathrm{RW}_{\times} \times(1-\min (T ; 0.5))$
Figure $6 \quad C R=R W \times 8 \%$

## Appendix 3: Risk Weight Scales

In this paper we consider securities that feature a long-term credit assessment therefore and as per article $263^{14}$ of the CRR the risk weights set out in Figure 4 and 5 shall apply. See the figure below which presents the scales of values for RW ${ }_{1}$ and RW $_{5}$ according to the seniority status and rating of the tranche:

Figure $7 \quad$ Risk Weights

|  | SENIOR TRANCHE |  | NON-SENIOR (THIN) TRANCHE |  |
| :---: | :---: | :---: | :---: | :---: |
| RATING ${ }^{15}$ | RW ${ }_{1}$ | $\mathrm{RW}_{5}$ | RW ${ }_{1}$ | RW5 |
| Aaa | 15\% | 20\% | 15\% | 70\% |
| Aa1 | 15\% | 30\% | 15\% | 90\% |
| Aa2 | 25\% | 40\% | 30\% | 120\% |
| Aa3 | 30\% | 45\% | 40\% | 140\% |
| A1 | 40\% | 50\% | 60\% | 160\% |
| A2 | 50\% | 65\% | 80\% | 180\% |
| A3 | 60\% | 70\% | 120\% | 210\% |
| Baa1 | 75\% | 90\% | 170\% | 260\% |
| Baa2 | 90\% | 105\% | 220\% | 310\% |
| Baa3 | 120\% | 140\% | 330\% | 420\% |
| Ba1 | 140\% | 160\% | 470\% | 580\% |
| Ba2 | 160\% | 180\% | 620\% | 760\% |
| Ba3 | 200\% | 225\% | 750\% | 860\% |
| B1 | 250\% | 280\% | 900\% | 950\% |
| B2 | 310\% | 340\% | 1050\% | 1050\% |
| B3 | 380\% | 420\% | 1130\% | 1130\% |
| Caa1 / Caa2 / Caa3 | 460\% | 505\% | 1250\% | 1250\% |
| Below Caa3 | 1250\% | 1250\% | 1250\% | 1250\% |

## Appendix 4: Rating Allocation for Individual Securities

In this paper we are taking a conservative approach to the ratings' allocation in line with regulation guidelines. In cases where several ratings were assigned to a security corresponding to different credit quality steps we have picked the lowest step and assigned it to the security. The corresponding risk weights are then used to calculate the minimum regulatory capital to be retained. The tables throughout this paper present categories of ratings according to this approach and in line with the different credit quality steps and use Moody's taxonomy for illustrative purposes only.

    ${ }^{4}$ Throughout this paper the weighted average maturity values were calculated based on cash flow projections computed as of the March $15,2023$.
    ${ }^{5}$ These options are quoted from the EBA framework guidelines (page 21, "Assumptions in relation to prepayments"), see the source link in the "Further reading" section at the end of this paper.
    ${ }^{6}$ These pricing scenarios are featured on the transaction's prospectus or term sheet and the base case represents the lowest prepayment speed assumption listed.
    ${ }^{7}$ In this paper we have picked categories (country, asset type) of RMBS and ABS securities that featured an observable historical average CPR and calculated the rolling yearly average in each case per option (b). The minimum was then selected in each case over the past 8 years (Q1 2015 to Q4 2022) as the longest observable period of data consistently across asset types.

[^2]:    ${ }^{8}$ The Miscellenaous category regroups the asset types that featured less than 10 securities for which a difference in RCF was observed with the exception of Dutch prime RMBS securities and Spanish transactions backed by Small Business Loans. Categories belonging to Portugal and Belgium are all included in this aggregate due to the smaller number of securities observed in these countries.

[^3]:    ${ }^{9}$ We are using the Moody's rating scale in order to illustrate the table. For the detail of the methodology used please refer to Appendix 3 and 4.

[^4]:    ${ }^{10}$ See Appendix 1 and 2 for these figures and further details

[^5]:    ${ }^{11}$ The list in this table is not exhaustive. Asset types that featured less than 10 securities for which a difference in RCF was observed with the exception of Dutch prime RMBS securities and Spanish transactions backed by Small Business Loans. Categories belonging to Portugal and Belgium are absent altogether.

[^6]:    ${ }^{12}$ See Appendix 3 for details
    ${ }^{13}$ See Appendix 2 for the detail of the RCF calculation and the impact of risk weights.

[^7]:    ${ }^{14}$ Article 263 of the CRR:
